

TVWebHook 1.0.68

What You Need + How to Create TradingView Webhook Alerts

1. What you need before the bot can trade

The bot does **not** generate buy/sell signals by itself. It only **receives** alerts and places orders on your exchange.

A. Free TradingView account

- Sign up at tradingview.com (free plan is enough for basic alerts).
- Free accounts have a limited number of alerts — enough to test and run a few strategies.
- Paid plans add more alerts and more complex conditions if you need them later.

B. A broker / exchange account with API access

- This bot is built for **Phemex** (via CCXT).
- You need API Key + Secret with trading permission (not withdraw-only).
- Use **testnet** keys first (SANDBOX_MODE true) before live money.
- Put the keys in your .env file (see Quick Start PDF).

C. This bot running on your PC

- The portable .exe or the .py script must be running and listening on port 5000.
- TradingView must be able to reach that URL (see “Public URL” below).

2. How a webhook alert works (simple picture)

1. Your chart / indicator condition becomes true on TradingView.
2. TradingView sends an HTTP POST to your bot's URL.
3. The bot reads the message (buy/sell + symbol), sizes the order, and places it on Phemex.

If the bot is offline, or the URL is wrong, no trade is placed.

3. You need a public URL for TradingView

TradingView's servers live on the internet. They cannot call `http://localhost:5000` on your PC.

Common options:

- **ngrok** (or similar tunnel): exposes your local port 5000 as a public https URL.
- A VPS / cloud PC with a public IP and port 5000 open.
- Your own domain pointed at the machine running the bot (e.g. `ranbot.site`).

Example webhook URL once the tunnel or domain is up:

```
https://your-public-host.example/
```

(The bot accepts POST on the root path /)

4. Step-by-step: create a TradingView alert with a webhook

Step 1 — Open a chart

Open the symbol you want (e.g. `BTCUSDT.P` or the chart you use for signals).

Step 2 — Create an alert

Click the Alert button (clock icon) or right-click the chart → Add alert.

Step 3 — Condition

Choose when it should fire: price crossing a level, indicator cross, strategy order, etc.

Step 4 — Notifications → Webhook URL

In the alert dialog, open the Notifications section.

Check **Webhook URL** and paste your public bot URL, for example:

```
https://your-tunnel-or-domain.example/
```

Step 5 — Message

Put the command the bot understands. Simplest form:

```
buy BTC/USDT:USDT
```

or

```
sell BTC/USD:BTC
```

JSON if you want a fixed lot size:

```
{"message": "buy BTC/USDT:USDT", "lotsize": 1}
```

Use the exchange symbol format the bot expects (CCXT style), e.g. BTC/USDT:USDT or BTC/USD:BTC — not only the TradingView ticker.

Step 6 — Create

Save the alert. When the condition hits, TradingView POSTs the message to your bot.

5. Message rules the bot understands

- One command per line: side then optional symbol.
- side = buy or sell (BUY_SELL_MODE in config can force or auto-pick side).
- If symbol is missing, the bot uses SYMBOL from configFile.json.
- SymLotOverride controls whether the webhook may change symbol and lotsize.

See the SymLotOverride Manual PDF for full override behavior.

6. Checklist before first live alert

- Bot is running (console shows “Waiting for TradingView alerts”)
- SANDBOX_MODE matches your keys (true = testnet, false = live)
- Public URL works (you can open the health page in a browser)
- Alert Webhook URL is exactly that public URL
- Message uses the correct CCXT symbol
- Account has enough margin in the right currency (USDT for linear, BTC for coin-m, etc.)

7. Common problems

- **Alert fired but no trade** — bot offline, wrong URL, or firewall blocking port 5000.
- **401 Failed to load API KEY** — wrong keys or SANDBOX_MODE mismatch.
- **TE_QTY_TOO_SMALL** — size below exchange minimum (bot tries to raise it).
- **Wrong margin currency** — coin-m needs free BTC (or base coin), not only USDT.
- **Two trades from one signal** — duplicate alerts or TV retry; use one alert per signal.

You need: free TradingView + exchange API keys + this bot reachable on a public URL. TradingView only sends the signal; the bot and broker do the trade.
